# OPTIMAL ENERGY CONCEPT FOR DECARBONISATIONOF SEA-BUCKTHORN PROCESSING PLANTS

Institute of Low-Carbon Industrial Processes, German Aerospace Center, Walther-Pauser-Strafe 5 – 03046 Cottbus (Germany)

# **INTRODUCTION**

The industrial sector accounts for 37% of the total global energy consumption and for a quarter of global energy system CO<sub>2</sub> emissions (1). Therefore, the Decarbonisation of the industrial sector plays a key role for the achievement of the objectives defined in the 2030 Climate and Energy framework of the European Union (2).

## **OBJECTIVE**

2

Optimal Decarbonisation concepts adapted to the industrial site integrate renewable sources and storage systems while minimizing investment and operating costs (3). In this work, an optimal energy supply system is defined for the decarbonization of a sea-buckthorn processing plant located in Herzberg (Germany).

# METHODOLOGY

### 1. Analysis of the industrial process:

- Gas boiler and steam generator
- PV plant: 55 kW<sub>p</sub>

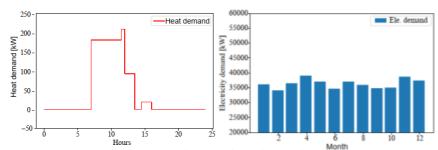

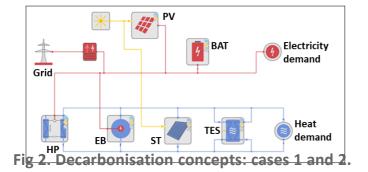

Fig 1. Daily heat demand and yearly electricity requirements for operation with steam.

#### 2. Decarbonisation energy concepts:

- Renewable sources (solar radiation)
- Energy conversion components: PV plant (PV), solar thermal (ST), heat pump(HP), electrical boiler (EB).
- Storage systems: battery (BAT), thermal storage (TES).

*Case 1*: Components for heat supply connected to the process. Air as HP heat source.

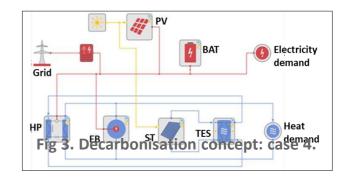

Case 2: Components for heat supply connected to the process. HP with geothermal heat source at 32°C.

Case 3: Case 1 with ST used only for TES charging.

Case 4: Case 3 with TES used only as HP heat source.

### 3. Modelling of energy concepts:

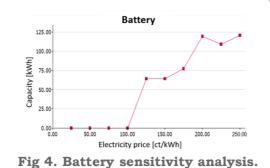

- Concept digitalization using a commercial optimization tool
- Implementation of an in-house operational logic
- Definition of operating and economic parameters for each component (electricity price = 16.75 ct/kWh)
- Coupled structural and operational optimization.

# 4 RESULTS

#### • Structural optimization:

COMPONENT	CASE 1	CASE 2	CASE 3	CASE
SIZING				
HP (kW)	140	140	155	70
EB (kW)	40	40	24	177
TES (kWh <sub>th</sub> )	150	158	130	145
BAT (kWh)	0	0	0	0
ST (m <sup>2</sup> )	75	75	75	75
PV (kW <sub>p</sub> )	190	190	190	190

### Operational optimizations:

PARAMETER	CASE 1	CASE 2	CASE 3	CASE 4
Operation costs (T€/year)	115	109	116	146
CO <sub>2</sub> emissions (t/year)	147	140	148	187
Investment (T€)	289	299	290	280
Payback time (year)	5.8	5.2	6	17.6

•				
	Analysis of the working fluid			
forthe reference case				

PARAMETER	STEAM	WATER
Operation costs (T€/year)	161	154
CO <sub>2</sub> emissions (t/a)	226	113

### CONCLUSIONS

5

- Operation with water instead of steam as working fluid shows a 15% reduction in the process heat demand that leads to a 5% reduction in operation costs and CO<sub>2</sub> emissions.
- The most appropriate Decarbonisation concept for the industrial site achieves a reduction of 25% in operation costs and 31% in CO<sub>2</sub> with an investment of 288.7 T€ and a payback time of 5.8 years.
- Battery integration is not profitable for electricity prices up to 100 ct/kWh.
- This analysis can be applied to other industrial processes and locations with adapted techno-economic parameters and operational logic.

### **AKNOWLEDGEMENTS**

This research was funded by the European Union's Horizon Europe project SINNOGENES (Storage innovations for green energy systems), under Grant Agreement No 101096992.
